

Chamaecrista glandulosa var. *mirabilis*

No common name

Family (Fabaceae)

Kingdom (Plantae)

Status (Endangered)

Description

Is a rare, endangered perennial herb or subshrub native to Puerto Rico. It thrives in open, acidic silica sands on the northern coast, particularly near the Tortuguero Lagoon, often standing 1-3 feet tall. Key features include yellow, solitary flowers with one larger petal and slender, wire-like stems.

Location/Habitat

Prostrate shrub endemic to the white silica sand substrates of the northern coast of Puerto Rico. It is primarily restricted to open, sunny areas near the Tortuguero Lagoon (Vega Baja), Dorado, and formerly Vega Alta, growing in highly acidic and permeable sandy soils.
