

Tectaria estremarana

No common name - a fern

Family (Tectariaceae)

Kingdom (Plantae)

Status (Endangered)

Description

A terrestrial fern with a thick, woody, erect rhizome covered in brown scales. It produces several fronds about 65–80 cm long, with light brown, slightly hairy stipes and oblong-ovate blades that are pinnatifid with 3–4 pairs of pinnae. The fronds have a softly hairy rachis, ciliate margins, and firm herbaceous tissue, with sori positioned closer to the midvein than to the edges of the lobes.

Location/Habitat

Found in northern Puerto Rico, specifically in Arecibo (including the Río Abajo Commonwealth Forest and the Arecibo Radio Telescope area) and in the municipality of . It occurs in karst environments such as sinkholes and areas near old quarries.
